- VAX/VMS QNA driver

Standard tables
Local driver storage
CONTROL INIT - INITIALIZE DEQNA DEVICE
CLONED OCB - INITIALIZE THE CLONED UCB
UNIT INIT - INITIALIZE THE DEQNA UNIT
FFI_INIT - FFI INTERFACE INITIALIZATION ROUTINE
XMT_FDT - TRANSMIT I/O OPERATION FDT ROUTINE
XMT_FTI START - START FAST INTERFACE TRANSMIT OPERATION
XMT_START - START TRANSMIT OPERATION
RCV_FDT - RECEIVE I/O OPERATION FDT ROUTINE
RCV_START - START RECEIVE I/O OPERATION
SUBROUTINES TO FIND SHR DATA STRUCTURE
ALT_START - ALTERNATE START I/O ROUTINE
SETMODE_FDT - SET MODE I/O OPERATION FDT DISPATCH ROUTINE
SHR_UCB - CREATE SHARED UCB
CHECK_PARAM - CHECK SHARED USERS PARAMETERS Standard tables

SHR UCB - CREATE SHARED UCB
CHECK PARAM - CHECK SHARED USERS PARAMETERS
SET MOLTIN - SET NEW MULTICAST ADDRESS LIST IN UCB
SENSEMODE FDT - SENSEMODE I/O FDT PROCESSING
READ LINE CTR - READ THE LINE COUNTERS
GET CHAR BUF - GET P2 CHARACTERISTICS BUFFER
CHECK BUFS - CHECK P1 AND P2 BUFFERS FOR WRITE ACCESS
CHECK P1 - CHECK P1 BUFFER ADDRESS FOR WRITE ACCESS
ALLOC P2BUF - ALLOCATE A P2 BUFFER AND CHARGE USER'S QUOTA
STARTIO - START I/O OPERATION
START - START UNIT'S PROTOCOL
SETUP MODE - SETUP THE TRANSMIT BUFFER TO INIT QNA
FILLREVLIST - FILL RECEIVE BUFFER LIST
START RECEIVE - START ANY RECEIVE REQUESTS PENDING
LOAD PORT - LOAD CSR'S WITH COMMAND REQUEST
QNA INTR - QNA INTERRUPT SERVICE ROUTINE
SCHED FORK - SCHEDULE THE FORK PROCESS
SCHED FORKC - SCHEDULE THE FORK PROCESS WITH R3 CLEAR
FORK PROC - Error and completion fork process handling

Table of contents

FORK PROC - Error and completion fork process handling RCV_ERROR - Process receive errors

RCV_ERROR - Process receive errors

XMT_ERROR - Process transmit errors

SUBROUTINES TO FIND SHR MATCH ON SOURCE ADDRESS

COPY_RCV - Copy a receive buffer for the PROMISCUOUS user

FINISH_XMT_FFI - Finish FAST interface transmit processing

FINISH_RCV_FFI - Finish FAST receive processing

FINISH_RCV_IO - Finish receive I/O processing

ASSEM_PKTS - Assemble receive packets

MOP_CTR_REQUEST - PROCESS MOP READ COUNTERS REQUEST

MOP_CTR_BUILD - BUILD THE MOP COUNTER RETURN MESSAGE

REG_DUMP - DEQNA ERROR LOG AND DIAGNOSTICS REGISTER DUMP

RESTART ROUT - PROCESS EXPIRATION OF RESTART TIMER

TOE_TIMER - PROCESS EXPIRATION OF TOE TIMER

TIMEOUT - TIMEOUT SERVICE ROUTINE

ALLOC_CDB - ALLOCATE THE CDB

SHUTDOWN QNA - SHUTDOWN QNA AND ALL UNITS

SHUTDOWN - SHUT DOWN UNIT

SHUTDOWN - SHUT DOWN UNIT

SHUTDOWN - SHUT DOWN UNIT
SHUTDOWN PROTYP - SHUT DOWN PROTOCOL TYPE
BLD_STOP_IRP - Build an IRP to reset promiscuous mode
BLD_STRT_IRP - Build a point-to-point startup IRP
BLD_IRP = Build an IRP routine
CLEANUP_SHR - CLEANUP ALL I/O ON SHARE DATA STRUCTURE
DELETE_SHR - DELETE SHR DATA STRUCTURE
CANCEL - CANCEL I/O ON UNIT
SUBROUTINES TO FIND SHR DATA STRUCTURE GIVEN PCB AND CHAN
FIND_POINT_UCB - Find the point to point UCB

		F 6
(65)	7111	ADD_MULTI - ADD UP ALL THE MULTICAST ADDRESSES
	7182	MOVE_MULTI - COPY THE MULTICAST ADDRESS LIST
(67)	7212	ROUTINES TO SAVE/RESTORE UCB'S MULTICAST ADDRESS LIST
(68)	7248	VALIDATE_P2 - VALIDATE P2 BUFFER PARAMETERS
(69)	7182 7212 7248 7417	CHANGE PARAM - UPDATE UCB/CDB BASED ON P2 BUFFER PARAMETERS

FACILITY:

VAX/VMS DEQNA QUEUE I/O DRIVER

ABSTRACT:

This module contains the DEQNA driver FDT routines, interrupt dispatcher, interrupt service and fork routines.

AUTHOR:

Rod Gamache 26-Jul-1983

MODIFICATION HISTORY:

V03-013 RNG0013 Rod Gamache 23-Jul-1984 Fix mode setup and shutdown.
Change default on ORB\$B_FLAGS to not set ACL queue present bit.

RNG0012 Rod Gamache 6-Jul-1984

Fix ALLOC_CDB to intialize the address of UCB unit 0.

Fix problems with re-starting FFI users and deleting V03-012 RNG0012 transmits on error.

Fix bug when disabling PROMiscuous mode in hardware.

Fix MOP read counters request.

V03-011 RNG0011 Rod Gamache 17-May-1984 Account for 4 bytes of CRC on received messages, when returning byte count from assemble pkt. Change the way the "set default" modifier for the

XQDRIVER VO4-000

Physical address is processed.

V03-010 RNG0010 Rod Gamache Fix the setup of the multicast address list for all users after the first.

V03-009 RNG0009 Rod Gamache 4-May-1984 Add DEV\$M_NET flag to device characteristics.

V03-008 RNG0008 Rod Gamache 19-Apr-1984 Fix call to EXESALOPHYCNTG to be absolute addressing.

V03-007 RNG0007 12-Apr-1984 Rod Gamache Fix problem with incorrect useage of the FFI interface. Also, return the Hardware Ethernet Address.

KPL0001 Peter Lieberwirth 9-Apr-1984
Use EXESALOPHYCNTG to allocate physically-contiguous IO buffer V03-006 KPL0001 required by u-VAX I on the QNA.

16-SEP-1984 00:37:44 VAX/VMS Macro V04-00 5-SEP-1984 00:20:54 [DRIVER.SRC]XQDRIVER.MAR;1

LMP0221 L. Mark Pilant, 27-Mar-1984 1 Change UCB\$L_OWNUIC to ORB\$L_OWNER and UCB\$W_VPROT to ORB\$W_PROT. V03-005 LMP0221 27-Mar-1984 12:02

RNG0004 Rod N. Gamache 6-Feb-1984 Set the XQ unit to RUN state when the QNA is initialized. V03-004 RNG0004 Make the SETMODE descriptor use a word for the length, rather than a longword.

TMK0002 Todd M. Katz 03-Feb-1984
When the DEQNA times out because of QBUS or device controller power failure, then call back all protocols which are using the FFI interface and have defined an FFI\$L ERROR asynchronous error routine. What this involves is noticing within the routine SHUTDOWN by means of the UCB\$V_POWER status bit that a power failure has occurred. In such a circumstance the port driver wants to call the asynchronous error routine of the protocol before doing anything else provided the protocol has initialized the FFI interface, defined an asynchronous error routine, and the UCB for the protocol is both on-line and initialized. V03-003 TMK0002 Todd M. Katz 03-Feb-1984

V03-002 TMK0001 03-Feb-1984 Todd M. Katz Make the following changes to the driver:

1. I have created a NI device dependent UCB extension within \$UCBDEF. This extension contains definitions for UCB\$L_NI_HWAPTR and UCB\$L_NI_MLTPTR, two new locations to be contained within the UCBs of all NI datalink drivers. I have therefore modified the XQDRIVER's UCB definition so that the DEQNA specific UCB fields begin immediately following the NI device dependent UCB extension.

UCB\$L_NI_HWAPTR is initialized when the CDB is first allocated to contain the address of CDB_G_HWA, the CDB location which contains the NI device's unique hardware address. UCB\$L_NI_MLTPTR is initialized within the unit

VQ VO

16-SEP-1984 00:37:44 VAX/VMS Macro V04-00 5-SEP-1984 00:20:54 [DRIVER.SRC]XQDRIVER.MAR;1

unitialization routine to contain the address of the table of multicast addresses defined for this protocol type. Both of these values must be accessible to the NI-SCS port driver. The NI-SCS port driver has access to the UCBs of the NI devices participating in SCS clusters, but it doesn't have initimate knowledge of how the UCBs and CDBs are layed out for each NI device. This UCB extension provides a means for the NI-SCS port driver to locate these values without knowing the exact layout of each of the NI device's UCB and CDB.

2. Whenever a protocol is to be started up on a DEGNA allow the initiator of the SETMODE+STARTUP to specify 0 receive buffers instead of the former minimum of 1. The effect on this protocol is that it must have a READ outstanding at all times in order to guarentee that it will receive all datagrams specifying its protocol. If a datagram was received for this protocol, and there wasn't a read outstanding, then because 0 receive buffers can be queued (or saved) for this protocol, the receive buffer would be deallocated to pool, and the message it contained lost.

This change is extremely useful for those users who are making use of the FFI interface provided by this port driver. Between the time the user issues a SETMODE+STARTUP, and the time the user initializes the FFI interface by calling FFI_INIT, it would be possible for the port driver to have received messages with this user's protocol, and to have queued them up to the appropriate UCB. Now, if the user never makes use of the QIO or ALTSTART interfaces, but just uses the FFI interfaces for communication, these messages, which are probably stale by this time, will never be received, and the buffers that contain them will effectively be lost forever. With this change, a user who wishes to do all his/her communication via the FFI interface can guarentee that a situation such as this can never arise, and buffers such as these can never be "lost".

4. Add the capability of requesting that the physical address of the DEQNA device be set to the default DECnet address, when the device is first initialized. This new capability is requested by means of the NMASC_LNMCN_SDF mode value specified within the modifier field of the NMASC_PCLI_PHA parameter.

V03-001 RNG0001 Rod Gamache 08-Dec-1983
Add new QNA 'hand-shake' to prevent driver from reading incorrect status from hardware.

                                                              Functional description:
                                                              This routine initializes the FFI interface. Currently the UCB must have been initialized prior to calling this routine, in the future this routine may have to initialize the UCB and DEQNA. Therefore, there may be a fork involved in the call to this routine.

                                     XMT_FDT - TRANSMIT I/O OPERATION FDT ROUTINE
                                     functional description:
                                     This routine sets up the internal function code for transmit and
                                     transfers control to the exec buffered I/O write FDT routine.
                                     The QIO parameters for WRITES are:
                                                 = Address of the data buffer
= Size of the data buffer
                                             P2 = Size of the data buffer
P5 = Address of buffer containing the destination address
                                      ** The driver can never do direct I/O on XMIT requests, because
                                     *** the QNA buffer address cannot begin on an odd byte boundary.

** Also, the FAST interface cannot operate on DIRECT I/O.
                                     Inputs:
                                              R3 = IRP address

```
.SBTTL XMT_FFI_START - START FAST INTERFACE TRANSMIT OPERATION
*** XMT_FFI_START - START FAST INTERFACE TRANSMIT OPERATION
  Functional description:
```

This routine is called to start a transmit operation. If the QNA is running then the request is given to the xmit wait queue for the QNA. If there is a free entry in the transmit ring and there are sufficient map registers to map the buffer then the request is given to the QNA immediately, else the request is left on the xmit wait queue until another request completes.

: Inputs:

R3 = CXB address R4 = FFI address

IPL = SYNCH (same as FIPL)

Outputs:

RO,R3 are destroyed. All other registers are preserved.

If the request cannot be queued, then the FFI\$L_XMIT_DONE entry is called immediately with the following:

RO = Status of transmit request R3 = CXB address R4 = FFI address

                             functional description:
                            This routine is called by the Executive to pass an "internal" IRP to the driver. "Internal" IRP's are those not built via QIO. These IRPs are used by higher level software used to request I/O and should not be confused with the IRPs built and passed by the Transport layer to NSP. The action here is to setup the IRP fields
                             as if the packet had been processed by the FDT routines.
                             Inputs:
                                      R3 = IRP address
R5 = UCB address
                                      All pertinent fields of the IRP are assumed to be valid.
                                      IPL = FIPL
                            Implicit inputs:
                                      IRP$L_SVAPTE(R3) = System VIRTUAL address (not physical PTE address)

```
.SBTTL SETMODE_FDT - SET MODE 1/O OPERATION FDT DISPATCH ROUTINE
```

SETMODE_FDT - SET MODE FDT PROCESSING

Functional description:

This is the fdt routine for setmode functions. There are three functions based on subfunction modifier bit.

NOTE: That there is no difference on a request to shutdown a line or a circuit. However, a request to startup a circuit is ignored completely.

The QIO parameters for SETMODE are:

P2 = Optional address of buffer descriptor for extended characteristics

The Subfunction modifiers are as follows:

- CHANGE MODE -- NO MODIFIER BIT. This function is done in the STARTIO routine. Control is passed to EXESSETMODE to validate the new mode buffer and queue the packet.
- INITIALIZE THE UNIT -- IOSM_STARTUP SET.
 This function is done partially here and the remainder in STARTIO. The action here is to pick up the user buffered I/O quota. The quota taken from the user is in IRP\$W BOFF. This value will be the IOSB+2 value at I/O done. The mailbox is enabled and a receive is started.
- SHUTDOWN UNIT -- 10\$M_SHUTDOWN SET.
 This function shuts down the unit and optionally resets the mode.
 A CANCEL I/O is performed, all outstanding I/O is completed, the message blocks are all returned and the unit is left in an idle state. This function cannot be done here and the FDT processing is that of all SETMODE operations. 3)
- 4) ATTENTION AST -- IOSM_ATTNAST SET. This function sets up an AST to be delivered when a change of status occurs on the QNA.

Inputs:

0790

= IRP ADDESS

R4 = PCB ADDRESS R5 = UCB ADDRESS

R6 = CCB ADDRESS R7 = FUNCTION CODE

AP = ADDRESS OF THE FIRST QIO PARAMETER

IPL = ASTDEL

Outputs:

R3 = IRP ADDRESS

R4 = PCB ADDRESS

.SBTTL SHR_UCB - CREATE SHARED UCB
       SHR_UCB - CREATE SHARED UCB
                functional description:
This subroutine creates a shared UCB if this is the first SHARED user of the
                particular protocol type. Else, the already created SHARED UCB is found and a shared data structure is added to the list of shared users of that protocol
                type.
                Inputs:
                        R3 = IRP address
R4 = PCB address
R5 = UCB address
                        R6 = CCB address
R7 = Function code
                        AP = Address of first function-dependent QIO parameter
                        IPL = FIPL
                Outputs:
                        RO = Status return for request
R1 = Bad parameter code (if bad parameter error code)
                        R2.R7 are destroyed.
                        All other registers are preserved.

                     Functional description:
                     Process read status and read counters requests.
                     The QIO parameters for SENSEMODE are:
     OCOB
OCOB
                            P1 = Optional address of quadword buffer
      OCOB
                            P2 = Optional address of buffer descriptor for extended characteristics
      OCOB
      OCOB
                     The SUBFUNCTION modifiers are as follows:
      OCOB
      OCOB
                            READ PARAMETERS -- NO MODIFIER.
                     1)
      OCOB
                            This function reads the QNA parameters and returns them to the user.
      OCOB
      OCOB
                            READ COUNTERS -- IOSM RD COUNT SET.
This function reads the GNA counters and returns them to the user.
                     2)
      OCOB
      OCOB
      OCOB
                            CLEAR COUNTERS -- IOSM_CLR_COUNT SET.
      OCOB
                            This modifier must be used with the read counters modifier to clear
      OCOB
                            the counters as they are read.

FILLRCVLIST - FILL RECEIVE BUFFER LIST
                                    .SBTTL FILLRCVLIST - FILL RECEIVE BUFFER LIST
                          FILLRCVLIST - FILL RECEIVE BUFFER LIST
                           functional description:
                          This routine fills the receive buffer list up to the quota allocated at unit initialization. It also gives any receive buffers allocated
                           to the receiver.
                           Inputs:
                                   R2 = Buffer Address (ADDRCVLIST ONLY)
R4 = CDB address
                                   IPL = FIPL
                          Outputs:
                                   RO-R2 is destroyed.
                                   All other registers are preserved.

                                5190
                                        This routine allocates a receive buffer in which to copy the a receive
                                        buffer for the PROMISCUOUS user.
                                          Inputs:
                                                R2 = Receive CXB address
                                                R4 = CDB address
R5 = UCB address of PROMISCUOUS user
                                                R6 = Address of receive ring entry
                        1A46
                                                IPL = FIPL
                                          Outputs:
                        1A46
                                                RO,R1,R3 are destroyed.
                                                All other registers are preserved.

       1813
1813
               ; FINISH_RCV_10 - Finish receive 1/0 processing
      functional description:
                          This routine completes a receive operation that has been matched with a
                          message block. After the receive has been completed the message free list
                          is filled and a receive is started if needed.
                           Inputs:
                                   R2 = receive CXB address
R3 = I/O packet address
                                   R4 = CDB address
                                   R5 = UCB address
                                   IPL = FIPL
                           Outputs:
                                   R5 is reset to UCB address from IRP
                                   The request is completed via I/O post.

.SBTTL ASSEM_PKTS - Assemble receive packets
                                       ASSEM_PKTS - Assemble receive packets
                                       functional description:
                                        This routine assembles all receive packets into one chain of complex
                                       buffers.
                                         Inputs:
                                               R4 = CDB address
                                               R7 = Receive ring address
                                               IPL = FIPL
                                        Outputs:
                                               RO = Status for request
R2 = Address of first receive buffer in chain
R6 = Address of last buffer in receive ring
                                               R1,R3 are destroyed.
                                               All other registers are preserved.
                              5496
5497
                                         Implicit Outputs:
                              5498
                              5499
                                               IRP$V_CHAIN and IRP$V_COMPLX bits set in IRP$W_STS if the receive
                               5500
                                               buffer is comprised of complex chained buffers.

                                          Functional description:
                                          This routine is used to shut down the XQ unit as a result of a SETMODE and SHUTDOWN. The action is to abort all I/O for the unit
                                           and then to clean up the unit data base.
                                          Inputs:
                                                   R3 = IRP address (SHUTDOWN_PROTYP entry only)
R4 = CDB address
H5 = UCB address
                                                   IPL = FIPL
                                          Outputs:
                                                   R3-R5 are preserved
                                                    RO-R2 are destroyed.
                                        SHUTDOWN PROTYP::

                                        BSBW
                         6800
                         6801
                                        Match found - clear inited bit and clean up all I/O on SHR data
                        6802
6803
                                        structure.
                                        We will Delete the SHR structure if this is a $DASSGN function
                         6805
                                        request. We will get this function when called from SYS$DASSGN
                                        system service and so we will have to delete the SHR structure
                         6806
                         6807
                                        and decrement the reference count. Note that the reference count
                        6808
6809
6810
                                        can never reach zero. Therefore, SYS$DASSGN will decrement the reference count on exit and we will be called again. This time
                                        there will be no match on the PID/CHAN and so the UCB will be
                                        cleaned up and deleted.

                                            functional description:
                                            This routine is called to combine all the per protocol type multicast addresses into a single list in the CDB. If the sum of all multicast
                                            addresses is greater than the QNA can manage, then an error is returned.
                                            Inputs:
                                                     R5 = UCB address
                                                     IPL = FIPL
                                            Outputs:
                                                     RO = Status return for request
                                                     R1,R2 are destroyed R3-R5 are preserved
                                            Implicit outputs:
                                                     CDB_B_MLTTBL = Number of multicast addresses in CDB_G_MLTTBL
CDB_G_MLTTBL = New multicast address list
                                                                                                           Add up all the multicast addresses
                                         ADD_MULTI:
                                                                 #*M<R3,R4,R6,R7>

Performance indicators !

Phase	Page faults	CPU Time	Elapsed Time
Initialization	36	00:00:00.07	00:00:01.40
Command processing Pass 1	1819	00:00:55.23	00:03:47.44
Symbol table sort Pass 2	478	00:00:04.90	00:00:55.84
Symbol table output Psect synopsis output	2	00:00:00.49	00:00:01.36
Cross-reference output Assembler run totals	2479	00:00:00.00	00:00:00.00

The working set limit was 3600 pages.
436246 bytes (853 pages) of virtual memory were used to buffer the intermediate code.
There were 250 pages of symbol table space allocated to hold 4250 non-local and 656 local symbols.
8230 source lines were read in Pass 1, producing 65 object records in Pass 2.
103 pages of virtual memory were used to define 92 macros.
